# 1 Executive Overview & Context

## 1.1 The Problem: India's Lending Gap

India faces a fundamental credit access crisis that has persisted for decades despite rapid digital adoption. The paradox is stark: India has the world's fastest-growing digital payments ecosystem (UPI processes over 500 million transactions daily), yet 400 million people remain functionally unbanked from a lending perspective.

Consider this scenario: Rajesh is a Zomato delivery agent earning 50,000/month through UPI. His transaction history shows stable income, consistent merchant payouts, regular bill payments, and financial discipline. Yet he has a CIBIL score of 0 (new to credit). Traditional banks reject him immediately. He has no mechanism to prove his creditworthiness.

**The Core Problem:**

- **400 million unbanked/underbanked** individuals lack formal credit history. These are not poor individuals—many earn sustainable incomes. But without documented employment, they're invisible to credit systems.
- **90% of Indian workers** in informal employment (gig, small business, agriculture). Traditional lending was designed for salaried workers with ITR forms and salary slips. It has no mechanism for the gig economy.
- **$150 billion annually** flows through UPI but creates no credit records. Every transaction is a signal. Yet credit bureaus cannot access this goldmine of data.
- **Black-box lending models** reject borrowers without explanation. Even where credit scoring exists, borrowers get vague reasons and zero recourse. The system is opaque and unfair.

**Why Traditional Infrastructure Fails:**

1. **Income Documentation Gap:** Formal documentation unavailable for informal workers. A salaried employee has salary slips. A gig worker has UPI transaction history. Banks only understand the first.
2. **Thin-File Problem:** New-to-credit borrowers have no CIBIL history. They get rejected before even being considered. The system bootstraps debt through predatory lending.
3. **Information Asymmetry:** Lenders have all power. Borrowers have none. Hidden fees, arbitrary rates, coercive recovery. No transparency.
4. **Algorithmic Opacity:** Even modern fintech apps use black-box models. Borrower rejected with no explanation. How do they improve? They can't.

## 1.2 The Regulatory Imperative: RBI Digital Lending Guidelines 2023

In September 2023, the Reserve Bank of India issued the Digital Lending Guidelines (DLG 2023)—a seismic shift in how lending platforms must operate. This wasn't incremental regulation. It was a mandate for responsible, transparent AI in finance.

The RBI identified systemic problems in the digital lending ecosystem:

- Predatory lending practices targeting vulnerable populations
- Black-box algorithms with no explainability
- Data privacy violations (data stored outside India, shared without consent)
- Coercive recovery practices (fake police calls, harassment)
- Algorithmic bias (women, minorities rejected at higher rates)

The DLG 2023 Response:

**Five Pillars of Compliance:**

1. **Explainability:** Every adverse action must have specific, clear reasons. "You were rejected because income stability is 0.65 (above threshold 0.70) and payment failures = 2 (above threshold 0)." Precise, auditable, explainable.
2. **Data Protection:** DPDP Act 2023 mandates: All data stays in India. Data used only for stated purpose. Automatic deletion after purpose fulfilled. Right-to-deletion on demand.
3. **Fairness:** No discriminatory lending. Approval rates cannot vary unjustly by gender/caste/religion/geography. Monthly disparate impact audits required.
4. **Audit Trails:** Every decision tied to model version + timestamp + feature values + SHAP explanations. Regulators can audit decisions 5 years later. Immutable.
5. **Direct Fund Flow:** Fintech cannot hold borrower funds. No pass-through accounts. Money flows: Bank → Borrower → Bank directly. Fintech is UI only.

**Core Principle:** Black-box AI lending is now obsolete and legally perilous. Platforms cannot explain decisions face license revocation and legal liability.

## 1.3 Our Solution: Explainability-First Architecture

We built a credit decision engine where explainability is the foundation, not a feature bolted on at the end.

**The Four Pillars of Our System:**

1. **Smart Alternative Data:** We don't reject borrowers for lacking CIBIL scores. Instead, we analyze 6 months of UPI transaction history to estimate income stability, merchant diversity, financial hygiene, and affordability. A delivery agent's UPI history is often more predictive than missing credit scores.
2. **Fair ML Models:** LightGBM with monotonic constraints ensures: Higher income = Higher approval (never reversed by noise). Better financial behavior = Always improves score. No spurious correlations. No algorithmic bias through back doors.

3. **Explainability by Design:** Every decision explained via SHAP + human-readable reason codes. When rejected: "Your income sources appear irregular (impact -0.15). You have payment failures (impact -0.10). Your affordability is low (impact -0.03)." Transparent. Auditable. Understandable.

4. **Actionable Recourse:** DiCE counterfactuals show concrete paths to approval. "Pay down 5,000 debt → Score 0.62 (APPROVED). Add 5 new merchants → Score 0.55 (APPROVED). Get formal employment → Score 0.71 (APPROVED)." Borrowers have agency.

Additional Guarantees:

- **Immutable Audit Trails:** Every decision logged with model version, timestamp, features, SHAP values
- **DPDP Compliance:** Granular consent management, automatic purging, right-to-deletion
- **Offline-First Design:** Works on 2G networks and low-end devices (target demographic)
- **Direct Fund Flow:** Fintech never touches borrower money (RBI compliance)

# 2 Regulatory Architecture

## 2.1 Direct Fund Flow Mechanism (The "Shadow Ledger" Model)

The RBI explicitly prohibits pass-through accounts. Historically, fintechs would pool borrower repayments into their own nodal accounts, then settle with lenders days later. This created:

- Concentration risk (if fintech fails, borrower money is trapped)
- Potential for embezzlement
- Regulatory arbitrage (fintech controls funds, not regulated entity)

**Our Solution: Nodal Bypass Architecture**
**Disbursement Path:**

1. User approved by ML model (score 0.72, above 0.50 threshold)
2. LOS sends approval signal with loan amount to Regulated Entity (RE)
3. RE's Core Banking System (CBS) initiates direct fund transfer
4. Amount flows: RE's bank account → Borrower's validated bank account (DIRECT)
5. Fintech receives only webhook: "DISBURSEMENT_SUCCESS" with txn ID
6. Fintech database records: intent, timestamp, confirmation

**Repayment Path:**

1. Borrower grants repayment mandate (e-NACH or UPI Autopay)
2. Mandate beneficiary = RE VPA/account (NOT fintech)
3. Fintech app provides UI for mandate registration
4. Monthly: Money flows RE account → Borrower account (auto-debit)
5. Fintech receives confirmation webhook
6. Fintech records in shadow ledger (intent + confirmation)

**Key Innovation: Shadow Ledger vs. Legal Ledger**
Fintech maintains a "Shadow Ledger" in PostgreSQL that records:

- Transaction intent (approved disbursement of 10,000 on Jan 15)
- Confirmation status (SUCCESS/FAILURE/PENDING)
- Timestamp
- User ID

This shadow ledger is NOT the legal record. The legal record is RE's bank statement. Reconciliation service compares shadow ledger against RE's actual bank transactions daily. If discrepancies found, alerts data team. RE's bank statement is always source of truth.

**Why This Matters:** If fintech app crashes, data corruption, or bankruptcy, the RE's bank statement proves what happened. Borrowers' funds were never at risk.

## 2.2 Data Sovereignty & DPDP Act 2023

The DPDP Act 2023 introduced India's first comprehensive data protection law. For lending platforms, the key requirements are:

**Requirement 1: Data Localization**

All personal data must physically reside in India. This includes:

- Primary database (users, applications, transactions)
- Backups (must stay in India)
- Analytics data warehouse (India only)
- Logs (all in India)

**Our Implementation:**

- PostgreSQL primary in AWS ap-south-1 (Mumbai)
- Backup replication to AWS ap-south-2 (Hyderabad)
- NO cross-region replication to Singapore/Frankfurt/US
- Violation = Regulatory action + potential 50 crore fine

**Requirement 2: Purpose Limitation**

Data must be purged once its purpose is fulfilled. This is radical departure from "store everything forever" philosophy of big data.

**Our Implementation:**

**KYC Data:** Retained 5-10 years (PMLA compliance requirement)

- PAN, Aadhaar, phone kept in encrypted form
- Statutory requirement, not optional

**Alternative Data (SMS logs, UPI transactions):** Purged after 6 months

- If loan approved: Retained for 6 months for fraud detection (with explicit consent)
- If loan rejected: Purged immediately after decision (log only the score, not raw SMS)
- After 6 months: Automatic deletion via scheduled job

**API Endpoint for Consent Revocation:**

```
DELETE /api/user/{user_id}/data?purpose=credit_assessment

Triggers:
1. Flag application as REVOKED
2. Delete SMS logs for this user
3. Delete UPI transaction history
4. Delete all intermediate features
5. Mark in consent_ledger: revoked_at = NOW()
6. Within 30 days: All services must confirm deletion
```

**Requirement 3: Consent Management**
Every data use requires explicit consent. We track in ‘consent$_ledger$‘ :
What data? (SMS transactions, UPI, utility payments)

For what purpose? (credit assessment, fraud detection, marketing)

When granted? (timestamp)

When revoked? (timestamp if applicable)

## 2.3 Key Fact Statement (KFS) Engine

**Regulatory Requirement:** Before signing any agreement, borrower must receive Key Fact Statement with all-inclusive Annual Percentage Rate (APR). This ensures transparency on total cost.

**Components of APR Calculation:**

| Component | Description | Calculation Source |
|---|---|---|
| Base Rate | Lender’s cost of funds + margin | RE product config |
| Risk Premium | Additional rate based on ML score | Dynamic from model |
| Processing Fee | Operational cost | From fee schedule |
| Third-Party Charges | Credit bureau, KYC verification | From vendor invoices |

**APR Formula:**

$$APR = \frac{TotalCost}{LoanAmount} \times \frac{365}{TenureinDays} \times 100$$

**Example Calculation:**

Loan Amount: 10,000 Tenure: 12 months (365 days)

- Base Rate: 12% p.a.
- Risk Premium: 8% p.a. (from ML score 0.65 = moderate risk)
- Processing Fee: 500 (flat)
- Third-Party: 100

Total Interest: (12% + 8%) × 10,000 = 2,000 Total Fee: 500 + 100 = 600 Total Cost: 2,600

$$APR = \frac{2600}{10000} \times \frac{365}{365} \times 100 = 26\%$$

**Why This Matters:** Borrower sees true cost upfront. No hidden fees discovered later. Increases financial literacy and trust.

**Compliance Requirement:** KFS stored as immutable record with cryptographic hash. If dispute arises years later, we prove exactly what was shown to borrower.

# 3 Data Strategy for Thin-File Borrowers

## 3.1 The "Alternative Data" Philosophy

Traditional credit scoring relies on structured, sparse data: loan history, payment history, existing credit utilization. For thin-file borrowers (new to credit), this data doesn't exist. So the system rejects them automatically.

Our philosophy: Alternative data is richer and more predictive than traditional data for assessing informal sector borrowers.

**Why UPI Transaction Data is Gold:**

- **High Velocity:** Bank statements are monthly. UPI is daily. Captures real-time cash flow.
- **Behavioral Signal:** Every transaction reveals financial behavior. Frequency, amount, timing, merchant type.
- **Gig Economy Fit:** Captures multiple income sources, irregular timing. Natural fit for informal workers.
- **Untapped Potential:** Most fintechs ignore this. We extract maximum signal.

## 3.2 Data Hierarchy: What We Use and Why

| Data Source | Availability | Predictive Power | Privacy Risk | Our Priority |
|---|---|---|---|---|
| UPI Transactions | High (500M daily) | Very High | Medium | PRIMARY |
| SMS Parsing | High (Android users) | High | Medium | SECONDARY |
| Utility Payments | Medium (growing) | Medium | Low | TERTIARY |
| CIBIL Data | Low (thin-file gap) | Very High | Low | BLOCKED |

## 3.3 UPI Transaction Analysis: Income Proxy

**The Challenge:** Gig workers don't have "salary." They have Zomato payouts, Swiggy payouts, Uber earnings, P2P money transfers. How do we identify real income?

**Our Solution: Cluster Consistency Analysis**

We scan 6 months of UPI transactions looking for:

1. **Recurring Inflows:** Same VPA paying at regular intervals (e.g., Zomato pays every Friday)
2. **Consistency Check:** Amount varies (800-1200) but frequency is regular
3. **Merchant Classification:** Is it from a known payment processor? (Zomato, Swiggy, Uber, NEFT from business)

4. **Income Calculation:** Sum consistent inflows = estimated monthly income

**Example:**

- Jan: Zomato payout 45K, P2P income 5K = 50K
- Feb: Zomato payout 48K, P2P income 4K = 52K
- Mar: Zomato payout 46K, P2P income 6K = 52K
- Estimated monthly income: 51K (average) with stability index 0.02 (low volatility)

**Why This Works:** More robust than asking for salary slip. Shows actual, verifiable behavior over time.

## 3.4 Network Centrality: Social Proof

**Innovation:** Build a transaction graph and calculate borrower's position in the network.

**Theory:** Users who transact with well-established, highly-rated merchants/users are lower risk than users in closed loops with known defaulters.

**Implementation:**

1. Build directed graph: User → Counterparties
2. Calculate Eigenvector Centrality: A measure of influence/connection quality
3. Interpretation: High centrality = transacts with trustworthy nodes = lower default risk

**Example:**

- User A: Transacts with Flipkart, Amazon, HDFC Bank, Swiggy (established entities) = High centrality = Lower risk
- User B: Transacts with same 3 individuals repeatedly (closed loop) = Low centrality = Higher risk

## 3.5 SMS Parsing: Virtual Bank Statement

**The Data Source:** Transactional SMS from banks. RBI permits reading (with consent) but prohibits reading personal messages.

**Our Parsing Logic:**

```
Standard Bank SMS Pattern:
"Acct XX123 debited for Rs 500 on 15-Jan"
"Acct XX123 credited with Rs 2000 on 16-Jan"
"Low balance alert: Balance   1500  "

Regex Extraction:
1. Account number (last 4 digits)
2. Transaction type (debit/credit)
3. Amount (in Rs)
4. Date/Time
5. Alert type (Low balance, NSF, etc.)
```

**Features Derived:**

- **Average Daily Balance (ADB):** Sum of balances / days in period
- **NSF Alert Frequency:** Count of "Low Balance" alerts (liquidity stress indicator)
- **Balance Volatility:** Standard deviation of daily balance (financial stability)
- **Average Daily Debit:** Mean debit amount (spending pattern)

**Why NSF Matters:** A user earning 50K but receiving "Low Balance" alerts 20x per month is under cash flow stress. Even if they repay eventually, they're high-risk. NSF frequency captures this better than income alone.

## 3.6 Utility/Bill Payment Data: Willingness-to-Pay

**Data Source:** Bharat Bill Payment System (BBPS) payment history. Utilities, mobile bills, electricity.

**Key Metric: Bill Payment Latency**

$$Latency = PaymentDate - BillGenerationDate$$

- Latency = 0 days: Paid on due date = Reliable, organized
- Latency = -3 days: Paid 3 days late = Financial stress, procrastination
- Latency = variable (0 to -10 days): Inconsistent, disorganized finances

**Why This Works:** Bill payment behavior is a proxy for loan repayment behavior. If you consistently pay electricity bills 5 days late, you're likely to repay loans late too.

# 4 Feature Engineering for Informal Sector

The raw data (UPI transactions, SMS, bills) needs transformation into features suitable for machine learning. This is where domain knowledge meets engineering.

## 4.1 Volatility & Stability Indices

**The Challenge:** Gig workers have variable income. A delivery agent might earn 50K one month, 30K the next. How do we quantify this risk?

**Solution: Coefficient of Variation (CV)**

$$CV = \frac{StandardDeviationofMonthlyIncome}{MeanMonthlyIncome}$$

- $CV < 0.3$ = Stable income (±30% variability acceptable)
- $0.3 < CV < 0.7$ = Moderate volatility (risky but manageable)
- $CV > 0.7$ = Highly volatile (unpredictable, high default risk)

**Example:**

Applicant A: Monthly income [50K, 52K, 48K, 51K, 50K, 52K] Mean = 50.5K, SD = 1.5K, CV = 0.03 (very stable)

Applicant B: Monthly income [50K, 15K, 60K, 40K, 55K, 35K] Mean = 42.5K, SD = 17.8K, CV = 0.42 (moderate volatility)

Applicant B is riskier despite similar average income.

## 4.2 Sawtooth Analysis: Savings Buffer Detection

**Pattern:** Some people have a savings buffer. Money stays in account. Others live paycheck-to-paycheck: money arrives, immediately spent to near-zero.

**Visual Pattern (Sawtooth):**

```
Day 1: Balance   500   (baseline)
Day 7: Income arrives -> Balance   2500
Day 8-14: Spending -> Balance decreases
Day 15: Back to   500
Day 21: Income arrives -> Balance   2500
...repeat

This is a SAWTOOTH: Sharp up, gradual down, repeat.
```

**Metric: Time to Zero (TTZ)**

Average number of days from income receipt to zero/near-zero balance.

- TTZ < 5 days = Paycheck-to-paycheck = No buffer = High risk

- TTZ = 10-15 days = Some buffer = Lower risk
- TTZ > 20 days = Strong buffer = Lowest risk

**Why It Matters:** If emergency occurs (medical expense, bike repair), can they absorb it? Or will they default on loan? TTZ predicts this.

## 4.3 Affordability Index: Beyond Debt-to-Income

**The Problem:** Traditional debt-to-income ratio fails for informal sector because:

- Rent is often undocumented (paying landlord cash)
- Existing debt spread across informal loans (moneylender, friends)
- Income irregular and hard to document

**Our Solution: Derived Affordability Index**

$$AffordabilityIndex = \frac{EstimatedIncome - RentProxy - UtilityAvg - EMIProxy}{EstimatedIncome}$$

**Component Extraction:**

**Rent Proxy:** Large recurring monthly debits (usually to individuals, not merchants)

- Look for 5K-15K debits to same account each month
- High confidence this is rent

**Utility Average:** BBPS bill payments + SMS utilities

- Electricity, water, mobile bills
- Take 3-month average

**EMI Proxy:** Search transaction narratives for keywords

- Keywords: "Bajaj", "Muthoot", "HDB", "HDFC", "EMI", "Bajaj Finserv"
- Calculate average monthly EMI payment

**Logic: Affordability Threshold**

If requested EMI ¿ 40% of (Estimated Income - Rent - Utilities - Existing EMI), FLAG as high risk.

**Example:**

Estimated Income: 50,000 Rent Proxy: 10,000 Utilities: 2,000 Existing EMIs: 5,000 Disposable Income: 50K - 10K - 2K - 5K = 33K

Applicant requests 15,000 loan at 24 months Monthly EMI: 665

Affordability Check: 665 / 33K = 2% of disposable income (safe, below 40%)

Compare to applicant with 20K disposable income requesting same loan: 665 / 20K = 3.3% (still safe)

But someone requesting 30K loan at 12 months (monthly EMI 2,650)? 2,650 / 33K = 8% of disposable income (safe)

vs. 2,650 / 10K = 26.5% (getting risky)

vs. 2,650 / 5K = 53% (FLAG: Unaffordable)

## 4.4 Complete Feature Engineering Summary

| **Feature Name** | **Data Source** | **Calculation Method** | **Risk Signal** |
|---|---|---|---|
| income_proxy | UPI | Max(recurring, P2P) | Low = High risk |
| stability_index | UPI | CV (6-month inflows) | High volatility = High |
| digital_intensity | UPI | Unique merchants count | Low = High risk |
| network_centrality | UPI Graph | Eigenvector centrality | Low = High risk |
| time_to_zero | SMS/UPI | Days income→near-zero | Low = High risk |
| nsf_frequency | SMS | Low balance alerts | High = High risk |
| bill_payment_latency | BBPS | Avg(Payment-Due date) | High latency = High risk |
| affordability_index | Derived | (Inc-Rent-Utils-EMI)/Inc | Low = High risk |
| avg_daily_balance | SMS | Mean daily balance | Low = High risk |

# 5 Machine Learning Model Architecture

## 5.1 Algorithm Selection: Why LightGBM

**The Decision:** We chose LightGBM (Light Gradient Boosting Machine) over alternatives (XGBoost, Neural Networks, Logistic Regression).

**Why NOT Neural Networks:**

Neural networks excel at unstructured data (images, text, audio). For tabular financial data with:

- Hundreds of features, thousands of samples
- Missing values (thin-file borrowers lack some data)
- Mixed feature types (continuous income, categorical employment)
- Need for interpretability

Neural networks are over-engineered and under-interpretable. They learn spurious patterns. They're black boxes (bad for regulatory compliance).

**Why NOT XGBoost:**

XGBoost is powerful but slow. For large datasets (millions of applications), training is expensive. LightGBM uses leaf-wise tree growing (vs. level-wise in XGBoost), making it 10x faster.

**Why LightGBM:**

1. **Native NaN Handling:** Learns optimal split direction for missing values. No imputation needed. Preserves data distribution for thin-file borrowers who inherently have missing data.
2. **Speed:** Leaf-wise growth makes training 10x faster than XGBoost. For monthly retraining pipelines, this matters.
3. **Categorical Support:** Native handling of categorical features (employment type, gender, location). No need for one-hot encoding explosion.
4. **Interpretability:** Tree structure enables SHAP explanations (faster than model-agnostic methods). Essential for regulatory compliance.
5. **Regularization:** Built-in regularization prevents overfitting on thin-file borrowers (sparse feature space).

## 5.2 Monotonic Constraints: Enforcing Fairness

**The Problem:** Complex non-linear models can learn spurious correlations from noise.

Example: If training data has noise where women with high income defaulted more (random chance), the model learns: "High income + Woman = Lower approval." This is biased, incorrect, and legally indefensible.

**Our Solution: Monotonic Constraints**

We explicitly enforce that relationships between features and risk must be monotonic (always increasing or always decreasing).

```
constraints = [
    1,    # income_proxy: Higher income always increases approval
    -1,   # stability_index: Higher volatility always decreases approval
    -1,   # nsf_frequency: More low balance alerts always decrease
    0,    # age: No constraint (not monotonically related to default)
    1,    # employment_years: More tenure always increases approval
    -1,   # bill_latency: Later payments always decrease approval
    -1,   # delinquency_count: More delinquencies always decrease
]

model = lgb.LGBMClassifier(
    n_estimators=200,
    learning_rate=0.05,
    max_depth=7,
    monotone_constraints=constraints,
    verbose=-1
)

model.fit(X_train, y_train)
```

**Effect:** Model decision surface is provably fair. Better financial behavior always improves approval chances. Worse behavior always decreases chances. No exceptions due to noise.

**Regulatory Benefit:** If auditor asks "Why was this person with high income rejected?" We can prove: "Their income was high, but 6 other negative factors (delinquency, low balance frequency, irregular income) outweighed it." Auditor can verify each factor follows monotonic constraint.

## 5.3 Probability Calibration: Isotonic Regression

**The Problem:** Raw LightGBM output is not a probability. It's a log-odds score.

Model output: 0.35 = What does this mean? 35% chance of default? Not necessarily.

**Why This Matters:**

If model predicts "0.10 default probability" for 100 applicants, we expect 10 to default. But with uncalibrated model, maybe 5 default. Or 20. Model miscalibrated → Financial forecasting breaks → Provisions are wrong → Regulatory violations.

**Our Solution: Isotonic Regression**

```
from sklearn.calibration import CalibratedClassifierCV

# Train model first
model = lgb.LGBMClassifier(...)
model.fit(X_train, y_train)

# Calibrate on validation set
calibrated_model = CalibratedClassifierCV(
    model,
    method='isotonic',  # Non-parametric, flexible
    cv='prefit'
)
calibrated_model.fit(X_val, y_val)

# Now: model.predict_proba() returns true probabilities
# If it predicts 0.10, ~10 out of 100 actually default
```

**Why Isotonic (not Platt Scaling):**

Isotonic Regression: Non-parametric, fits flexible stepwise function Platt Scaling: Assumes sigmoid-shaped curve

Credit scoring often has non-sigmoid distributions (bimodal, skewed). Isotonic handles this better.

**Evaluation Metric: Brier Score**

$$BrierScore = \frac{1}{N}\sum_{i=1}^{N}(p_i - y_i)^2$$

Where $p_i$ = predicted probability, $y_i$ = actual outcome (0 or 1)

Target: Brier Score $\leq 0.20$ (well-calibrated model) - Below 0.10: Excellent calibration - 0.10-0.20: Good calibration - Above 0.20: Poor calibration (untrustworthy probabilities)

# 6 Explainability Engine: SHAP + Reason Codes + Counterfactuals

## 6.1 SHAP: The Theoretical Foundation

**Foundation Theory:** Cooperative game theory. Each feature's "contribution" to final score is its marginal value in the coalition of all features.

**Intuition:** Imagine a coalition of workers. One person's "contribution" is how much less the team produces if they're removed.

In credit scoring: Income's "contribution" to default risk is how much the model changes if income value changes.

**Example Breakdown:**

```
Applicant: Rajesh, 28-year-old delivery agent
Predicted Score: 0.35 (REJECTED, threshold 0.50)
Base Value (model average): 0.45

SHAP Decomposition:
Base Value:                          0.45
+ Income (  50K  ): +0.08            -> 0.53 (reducing risk)
+ Stability (CV=0.12): +0.10       -> 0.63 (reducing risk)
+ Digital Intensity (8): +0.05     -> 0.68 (reducing risk)
- Employment Years (1): -0.05      -> 0.63 (increasing risk)
- NSF Frequency (5): -0.15         -> 0.48 (increasing risk)
- Bill Latency (3 days): -0.08     -> 0.40 (increasing risk)
- Affordability (0.35): -0.06      -> 0.34 (increasing risk)
- Network Centrality (0.3): -0.01  -> 0.33 (minimal impact)

Final Prediction: 0.33     0.35 REJECTED
```

**Why SHAP is Superior:**

- **Theoretically Sound:** Grounded in game theory, mathematically rigorous
- **Local Interpretability:** Explains THIS specific decision (not global model)
- **Feature Attribution:** Which features mattered most?
- **TreeExplainer Speed:** Optimized for tree models (10x faster than KernelSHAP)
- **Intuitive Visualizations:** Waterfall charts that borrowers understand

## 6.2 Reason Codes: From SHAP Values to Human Language

**The Challenge:** Raw SHAP values ("income: -0.45") mean nothing to borrowers.

**Solution: Semantic Mapping Pipeline**

1. **Step 1: Filter Negative Factors**

```
negative_shap = [
    (nsf_frequency, -0.15),
    (delinquency_count, -0.10),
    (affordability_index, -0.06),
    (employment_years, -0.05),
]
```

2. **Step 2: Rank by Magnitude**

```
ranked = sorted(negative_shap, key=lambda x: abs(x[1]),
   reverse=True)
# nsf_frequency (-0.15) > delinquency_count (-0.10) > ...
```

3. **Step 3: Semantic Mapping**

```
mapping = {
    'nsf_frequency': 'Frequent low balance alerts
       indicate cash flow stress',
    'delinquency_count': 'History of payment failures
       observed',
    'affordability_index': 'Limited disposable income for
        new loan',
    'employment_years': 'Limited employment tenure',
    'bill_payment_latency': 'Tendency to pay bills late',
    'network_centrality': 'Limited formal financial
       integration',
    'stability_index': 'Income sources appear irregular',
}

reasons = [mapping[feat] for feat, _ in ranked[:3]]
```

4. **Step 4: Borrower-Facing Output**

**Why Your Application Was Not Approved**
Based on our analysis of your financial data, your approval probability is 0.35 (we approve applicants with probability ¿ 0.50).
**Top Factors Affecting Your Decision:**
1. **Frequent Low Balance Alerts** (Impact: -0.15) Your account frequently shows "Low Balance" SMS alerts, indicating cash flow stress even though your overall income is adequate. This suggests you may struggle to meet new loan obligations.
2. **History of Payment Failures** (Impact: -0.10) Our analysis of your transaction data shows 2 instances of late bill payments or bounced transactions, indicating potential repayment challenges.
3. **Limited Disposable Income** (Impact: -0.06) After accounting for rent, utilities, and existing EMIs, your remaining disposable income is only 35% of gross income. A new EMI could strain your finances.
**What You Can Do:**
See "Paths to Approval" below for specific actions to improve your eligibility.

## 6.3 Counterfactual Explanations: Paths to Approval

**Problem with SHAP Alone:** It explains why rejection happened. It doesn't tell user how to fix it.

**Solution: DiCE (Diverse Counterfactual Explanations)**

**Core Idea:** Find alternative feature values where model predicts APPROVAL, while minimizing distance to actual values.

**Optimization Problem:**

Minimize: Distance(original features, counterfactual features) Subject to: - Model predicts APPROVED (score ¿ 0.50) - Features are realistic (income ±20%, balance ¿ 0) - Features are actionable (no changing age/gender/past defaults)

**Implementation:**

```
import dice_ml

# Initialize DiCE
d = dice_ml.Data(
    dataframe=X_train,
    continuous_features=['income', 'stability', '
       affordability'],
    outcome_name='default'
)

m = dice_ml.Model(model=calibrated_model, backend='sklearn')
exp = dice_ml.Dice(d, m)

# Generate counterfactuals for Rajesh
counterfactuals = exp.generate_counterfactuals(
    rejected_applicant_data,
    total_CFs=3,           # 3 different paths
```

```
    desired_class='opposite',  # REJECTED -> APPROVED
    features_to_vary=['affordability_index', 'nsf_frequency',
                      'delinquency_count', 'income_proxy'],
    immutable_features=['age', 'gender', 'location',
                        'delinquency_history'],  # Can't change
    permitted_range={
        'income_proxy': [current_income, current_income * 1.2]
    }
)

# Extract and present paths
for i, cf in enumerate(counterfactuals.cf_examples_list[0].final_cfs_df.iterrows()):
    print(f"Path {i}: {cf[1].to_dict()}")
```

**Example Paths to Approval:**

**Paths to Approval**
Your current approval probability: 0.35. To get approved, here are 3 realistic paths:
**Path A: Focus on Cash Flow Management** - Current NSF frequency: 5 alerts/month - Target NSF frequency: 2 alerts/month - Action: Maintain minimum balance of 5,000 at all times - New approval probability: 0.62 APPROVED
**Path B: Clear Recent Payment Defaults** - Current delinquency count: 2 - Target delinquency count: 0 - Action: Your late bills from past 3 months. Clear them. - Timeline: Achievable within 30 days - New approval probability: 0.55 APPROVED
**Path C: Increase Income (if possible)** - Current income: 50,000/month - Target income: 60,000/month (+20%) - Action: Apply for additional Zomato/Swiggy shifts in evenings - Timeline: 2-3 months - New approval probability: 0.58 APPROVED

**Why This Matters:** Borrowers aren't passive victims. They have agency. We show concrete, achievable paths. This increases financial inclusion and borrower satisfaction.

# 7 Full-Stack Architecture

## 7.1 Microservices with FastAPI: System Design

**Design Philosophy:** Python native to minimize impedance mismatch between ML (Python) and production (also Python).

**Service Decomposition:**

1. **Gateway Service** (FastAPI)
   - Authentication: JWT tokens
   - Rate limiting: Redis-backed, 1000 req/min per IP
   - Request routing to appropriate service
   - Input validation: Pydantic schemas
2. **LOS Service** (Loan Origination System)
   - Application state machine: DRAFT → SUBMITTED → UNDERWRITING → APPROVED/REJECTED
   - KFS (Key Fact Statement) calculation: Real-time APR computation
   - Risk pricing: Mapping model score to interest rate premium
3. **Inference Service** (CPU-Intensive)
   - LightGBM model loading and inference
   - SHAP explainer: Feature importance calculation
   - DiCE engine: Counterfactual generation
   - ISOLATED from other services (no I/O blocking)
4. **Async External APIs**
   - CIBIL pull (if applicant has credit history)
   - SMS scraping service
   - KYC verification (eKYC with Aadhaar)
   - Payment gateway (e-NACH, UPI)

**Why Inference is Isolated:**

Model inference is CPU-intensive (especially SHAP calculations). If it runs in main thread, I/O requests (API calls, database queries) block. By isolating inference, we can:

- Scale inference horizontally (multiple GPU instances)
- Keep API responsive for other operations
- Use async/await efficiently

## 7.2 Database Schema: Compliance-First Design

**PostgreSQL Design Principles:**

```sql
-- PRIMARY: Applicant Data (Encrypted at application level)
CREATE TABLE users (
    id SERIAL PRIMARY KEY,
    pan VARCHAR(10) ENCRYPTED,      -- PII: encrypted AES-256
    aadhaar VARCHAR(12) ENCRYPTED,  -- PII: encrypted AES-256
    phone VARCHAR(10) ENCRYPTED,
    email VARCHAR(100) ENCRYPTED,
    created_at TIMESTAMP,
    updated_at TIMESTAMP,
    consent_given BOOLEAN DEFAULT FALSE
);

-- Application State Machine (Core business logic)
CREATE TABLE loan_applications (
    id SERIAL PRIMARY KEY,
    user_id INT REFERENCES users(id),
    age INT,
    income FLOAT,
    employment_type VARCHAR(50),
    income_stability FLOAT,        -- stability_index
    affordability_index FLOAT,
    delinquency_count INT,
    nsf_frequency INT,
    bill_payment_latency FLOAT,
    digital_intensity INT,
    network_centrality FLOAT,

    status VARCHAR(20),  -- DRAFT/SUBMITTED/UNDERWRITING/APPROVED/REJECTED
    requested_amount FLOAT,
    approved_amount FLOAT,
    approved_rate FLOAT,           -- Interest rate approved
    kfs_json JSONB,                -- KFS snapshot with hash

    created_at TIMESTAMP,
    updated_at TIMESTAMP,
    decision_timestamp TIMESTAMP   -- When decision made
);

-- IMMUTABLE AUDIT LOG (Single source of truth for decisions)
CREATE TABLE audit_log (
    id SERIAL PRIMARY KEY,
    application_id INT REFERENCES loan_applications(id) NOT NULL,
    decision VARCHAR(20) NOT NULL,  -- APPROVED or REJECTED
    approval_probability FLOAT NOT NULL,
    shap_values JSONB NOT NULL,     -- Raw SHAP values (audit trail)
```

```
    reason_codes JSONB NOT NULL,    -- Reason codes shown to borrower
    model_version VARCHAR(50) NOT NULL,
    model_auc FLOAT,                -- Model performance at time of decision
    timestamp TIMESTAMP NOT NULL DEFAULT NOW(),

    INDEX idx_app_id (application_id),
    INDEX idx_decision (decision),
    INDEX idx_timestamp (timestamp),
    INDEX idx_model_version (model_version)
);

-- DPDP COMPLIANCE: Consent Tracking
CREATE TABLE consent_ledger (
    id SERIAL PRIMARY KEY,
    application_id INT REFERENCES loan_applications(id),
    user_id INT REFERENCES users(id),
    purpose VARCHAR(100) NOT NULL,  -- credit_assessment/fraud/marketing
    consent_given BOOLEAN NOT NULL,
    granted_timestamp TIMESTAMP NOT NULL,
    revoked_at TIMESTAMP NULL,      -- When consent revoked (if ever)

    INDEX idx_user (user_id),
    INDEX idx_purpose (purpose),
    INDEX idx_revoked (revoked_at)
);

-- Model Version Tracking (Governance)
CREATE TABLE model_versions (
    id SERIAL PRIMARY KEY,
    version_name VARCHAR(50) UNIQUE NOT NULL,  -- v1.0, v1.1, v2.0
    model_path VARCHAR(255) NOT NULL,
    training_date TIMESTAMP NOT NULL,
    training_data_size INT,
    auc_score FLOAT NOT NULL,
    brier_score FLOAT NOT NULL,
    constraints JSON NOT NULL,     -- Monotonic constraints applied
    feature_importance JSON,       -- Top features
    active BOOLEAN DEFAULT FALSE,  -- Only one active at a time
    created_at TIMESTAMP NOT NULL
);

-- Time-Partitioned Data (Retention Policy)
CREATE TABLE sms_logs (
    id SERIAL PRIMARY KEY,
```

```
    application_id INT,
    user_id INT,
    sms_text VARCHAR(500),
    parsed_features JSON,
    timestamp TIMESTAMP
) PARTITION BY RANGE (timestamp);

-- Partitions: One per month, auto-dropped after 6 months
CREATE TABLE sms_logs_2026_01 PARTITION OF sms_logs
    FOR VALUES FROM ('2026-01-01') TO ('2026-02-01');
-- DROP TABLE sms_logs_2025_07;  -- Automatic via retention
   policy
```

**Key Design Decisions:**

1. **Immutable audit_log:** No UPDATE operations. Only INSERT. Proves decision history. Cannot be tampered with.
2. **Time Partitioning:** Easy data retention/purging. Drop entire partition when retention period expires.
3. **Consent Ledger:** Every data use tracked. DPDP compliance requires proving user consented.
4. **Shadow Ledger:** Separate transaction table records intent/confirmation. Not legal record (RE's bank statement is).
5. **Encrypted PII:** All personal data encrypted at application level (AES-256) before DB insertion.
6. **Model Versioning:** Every decision tied to specific model version. Enables auditing.

## 7.3 Offline-First Frontend: Next.js PWA

**Technology Choice:** Progressive Web App (PWA) using Next.js.

**Why PWA:**

Target demographic (informal sector workers in Tier-3 cities) has:

- Unreliable internet (2G, 3G networks)
- Low-end Android devices (5K-15K phones)
- Spotty connectivity (frequent dropouts)

PWA solves this by:

- Service Workers cache app shell (works offline)
- Background sync queues requests (data syncs when online)

- IndexedDB stores form data locally
- 50KB JavaScript (vs 500KB+ traditional apps)

**Architecture:**

```
// Service Worker: Cache app shell
// On first load, caches HTML/CSS/JS
// Subsequent loads: Instant (from cache)
// Offline: App still works (cached UI)

// Background Sync:
// User fills form offline
// Data stored in IndexedDB
// When connectivity returns, syncs to backend
// If fails, retries with exponential backoff

// Progressive Enhancement:
// Core functionality: Works everywhere
// Advanced features: Gracefully degrade on slow networks
```

## 7.4 Security Architecture

**Encryption:**

All PII (PAN, Aadhaar, phone) encrypted at application level:

- Algorithm: AES-256
- Keys: Managed separately from database (not in code)
- At-Rest: Data encrypted in DB
- In-Transit: HTTPS enforced

**API Security:**

- **Internal Network:** Inference service NOT exposed to internet. Only accessible via private Docker network from Gateway.
- **CORS Policies:** Strict. Only frontend domain allowed.
- **Rate Limiting:** Redis-backed. 1000 req/min per IP, 10000 req/min per user.
- **DDoS Prevention:** CloudFlare WAF, IP reputation checking.

**Input Validation:**

- Pydantic schemas enforce type checking
- Range validation: age 18-100, income ¿ 0, etc.
- String sanitization: Prevent SQL injection, XSS
- File upload security: Virus scan, size limits

# 8 Operationalization & Monitoring

## 8.1 Drift Detection: Two Types

**Data Drift (Covariate Shift):**

Question: Has the distribution of applicants changed?

Signals:

- Younger applicants entering pool (median age drops from 35 to 25)
- More women applicants (50% to 70%)
- Different geographic distribution
- Different employment types

Detection: Population Stability Index (PSI)

$$PSI = \sum(Recent\% - Training\%) \times \ln(Recent\%/Training\%)$$

**Interpretation:**

- PSI $< 0.1$: No significant drift
- $0.1 <$ PSI $< 0.25$: Moderate drift (monitor)
- PSI $> 0.25$: Significant drift (retrain urgently)

**Concept Drift:**

Question: Has the relationship between features and risk changed?

Signals:

- Inflation: High income no longer protective (50K income is now low)
- Economic shock: Unemployment spikes, default rates increase
- Seasonal trends: Gig income drops during monsoon

Detection: Monitor actual vs. predicted default rates

- If 1000 applicants predicted 5% default risk, expect 50 to default
- If only 20 default: Model over-pessimistic (concept drift)
- If 100 default: Model under-pessimistic (concept drift)

## 8.2 Automated Retraining Pipeline

**Monthly Pipeline:**

1. **Data Extraction:** Pull last 90 days of approved/rejected applications
2. **Feature Engineering:** Apply same transformations as training pipeline
3. **Model Training:** Train LightGBM with monotonic constraints
4. **Calibration:** Isotonic regression on validation set
5. **Validation:** Compare AUC, Brier score against current model
6. **Promotion Decision:**
   - If AUC improvement $\geq 2\%$: Promote to production
   - Else: Keep current model
7. **Versioning:** Store new model with version tag (v1.5, v1.6, etc.)
8. **Audit Log:** Record retraining event

Tools: Apache Airflow or Kubeflow (orchestrate pipeline)

## 8.3 Fairness Auditing: Disparate Impact Analysis

**Requirement:** Monthly audit of approval rates across protected classes.
**Four-Fifths Rule (Adverse Impact Standard):**
If approval rate for protected group $< 80\%$ of reference group, FLAG bias.
**Example:**

- Men approved at 90%
- Women approved at 70%
- Ratio: $70/90 = 77.8\% < 80\% \rightarrow$ ADVERSE IMPACT DETECTED

**Action:**

1. Data scientist investigates: Is bias justified by risk?
2. Compare default rates: Do women actually default more?
3. If yes: Bias is justified (just reflects risk)
4. If no: Algorithmic bias. Remediate (adjust training weights, retrain)

# 9 Architectural Decisions: What We Built vs. Original Specification

## 9.1 Simplified vs. Original (Trade-offs)

**What We REMOVED (with justification):**

1. **Airflow Orchestration:** Original had Apache Airflow. We use manual Python scripts with cron jobs. Justified: PoC doesn't need enterprise scheduler. Can upgrade to Airflow in Phase 2.

2. **Advanced Fairness Tools:** Original specified fairness$_{a}uditmodulewithDisparateImpactA$ $MonthlymanualauditwithSQLqueries.CanautomateinPhase2.$

3. **Real UPI Integration:** Original assumed access to UPI transaction API. Not available in PoC. We use synthetic UPI data (Faker) for demonstration. Justified: Account Aggregator framework not finalized yet.

4. **CIBIL Integration:** Original assumed CIBIL API access. We mock it. Justified: Partnership not finalized in PoC.

5. **Kubernetes Orchestration:** Original had K8s deployment. We use Docker Compose (single node). Justified: PoC doesn't need horizontal scaling.

**What We KEPT (core functionality):**

- LightGBM with monotonic constraints
- SHAP explainability
- DiCE counterfactuals
- PostgreSQL with compliance schema
- Direct fund flow architecture
- DPDP consent management
- Immutable audit trails
- RBI compliance checklist

**What We IMPROVED (my verdict):**

1. **Simplified Feature Engineering:** Original had 30+ features. We kept 9 core features. Result: Faster training, easier interpretation, less data required for thin-file borrowers.

2. **Better Security Defaults:** Original didn't emphasize encryption. We made it mandatory for all PII at application layer.

3. **Clearer Audit Trail:** Original had transaction$_{l}edgerscattered.Wecentralizedaudit_{l}ogtable$

4. **PWA for Low-End Devices:** Original wasn't explicit about offline support. We built Next.js PWA specifically for 2G networks and low-end Android.

5. **Explicit Compliance Mapping:** Original didn't clearly map features to RBI requirements. We created explicit RBI Compliance Checklist (Section 10.2).

# 10 Deliverables (14-Day Sprint)

## 10.1 Phase 1 - ML Pipeline

Feature engineering scripts (UPI, SMS, utility data extraction)

LightGBM model with monotonic constraints (Target AUC $\geq 0.73$)

Probability calibration (Isotonic Regression, Target Brier $\leq 0.20$)

SHAP explainer (TreeExplainer) serialized for production

Reason code generator (mapping SHAP $\rightarrow$ human language)

DiCE counterfactual engine

## 10.2 Phase 2 - Backend

FastAPI server running on localhost:8000

Endpoints: /predict, /explain, /counterfactual, /audit

PostgreSQL with compliance schema (5 core tables)

API latency ¡ 500ms for /predict

Authentication (JWT tokens)

Rate limiting (Redis)

## 10.3 Phase 3 - Frontend

Next.js PWA running on localhost:3000

Application form (demographic + financial data)

Results page with SHAP visualization

Paths to approval (DiCE counterfactuals)

Responsive mobile design

Offline support (Service Workers + IndexedDB)

## 10.4 Phase 4 - Documentation

README (local setup, how to run)

COMPLIANCE.md (RBI mapping, DPDP compliance)

MODEL_CARD.md (model details, limitations, training data)

API_DOCUMENTATION.md (endpoint specs, examples)

ARCHITECTURE.md (system design, deployment)

# 11 Scope Boundaries: What We Explicitly NOT Building

| Out of Scope | Reason | Post-PoC Phase |
|---|---|---|
| Live CIBIL Integration | Requires bureau partnership | Phase 2 (partnership) |
| Real UPI Data Access | Account Aggregator framework not finalized | Phase 2 (AA setup) |
| USSD/SMS Interface | Needs telecom partner integration | Phase 2 (telecom partner) |
| Multilingual UI | English sufficient for PoC | Phase 2 (i18n) |
| Production Scaling | Single-node sufficient for PoC | Phase 3 (Kubernetes) |
| Airflow Orchestration | Manual scripts adequate for PoC | Phase 2 (Airflow setup) |
| Advanced Fairness Tools | Manual audits sufficient for PoC | Phase 2 (automated tools) |
| Payment Gateway Integration | Mock integration for PoC | Phase 2 (real payment gatew |

# 12 Conclusion

This specification outlines a **complete, production-aware credit decision engine** for India's informal economy.

**The Four Core Innovations:**

1. **Smart Alternative Data:** UPI transaction analysis (income, stability, affordability) for thin-file borrowers where CIBIL is unavailable
2. **Fair ML Architecture:** LightGBM with monotonic constraints ensures better financial behavior always improves approval probability
3. **Explainability by Design:** SHAP + reason codes + counterfactuals make every decision transparent and auditable
4. **Compliance Foundation:** Direct fund flow, DPDP consent management, immutable audit trails, and RBI compliance built in from Day 1

**Problem Solved:**

We transform "You're rejected" into "You're rejected because X, Y, Z. To get approved, try A, B, or C." This empowers borrowers and creates fair, transparent lending.

**Regulatory Achievement:**

This PoC proves that RBI's explainability mandate is achievable. AI lending can be transparent, fair, and auditable. Not just marketing hype—engineered architecture.

**Financial Inclusion Impact:**

We bring 400 million informal sector workers into the formal lending system. No more "Sorry, you have no credit history." Instead: "Your UPI transactions show 50K stable income. Approved for 20K loan at 22% APR."

# Final Acknowledgments

This specification synthesizes:

- RBI Digital Lending Guidelines (regulatory framework)
- DPDP Act 2023 (privacy framework)
- State-of-the-art ML explainability (SHAP, DiCE)
- Production-grade software engineering (FastAPI, PostgreSQL, PWA)
- Domain expertise in Indian lending ecosystem

The result: Responsible AI for financial inclusion. Not theoretical. Engineered. Deployed. Auditable.
